# Motivation

- \* 2(AX18) 4(AX08)
- Times a year
- \* Every 40 km

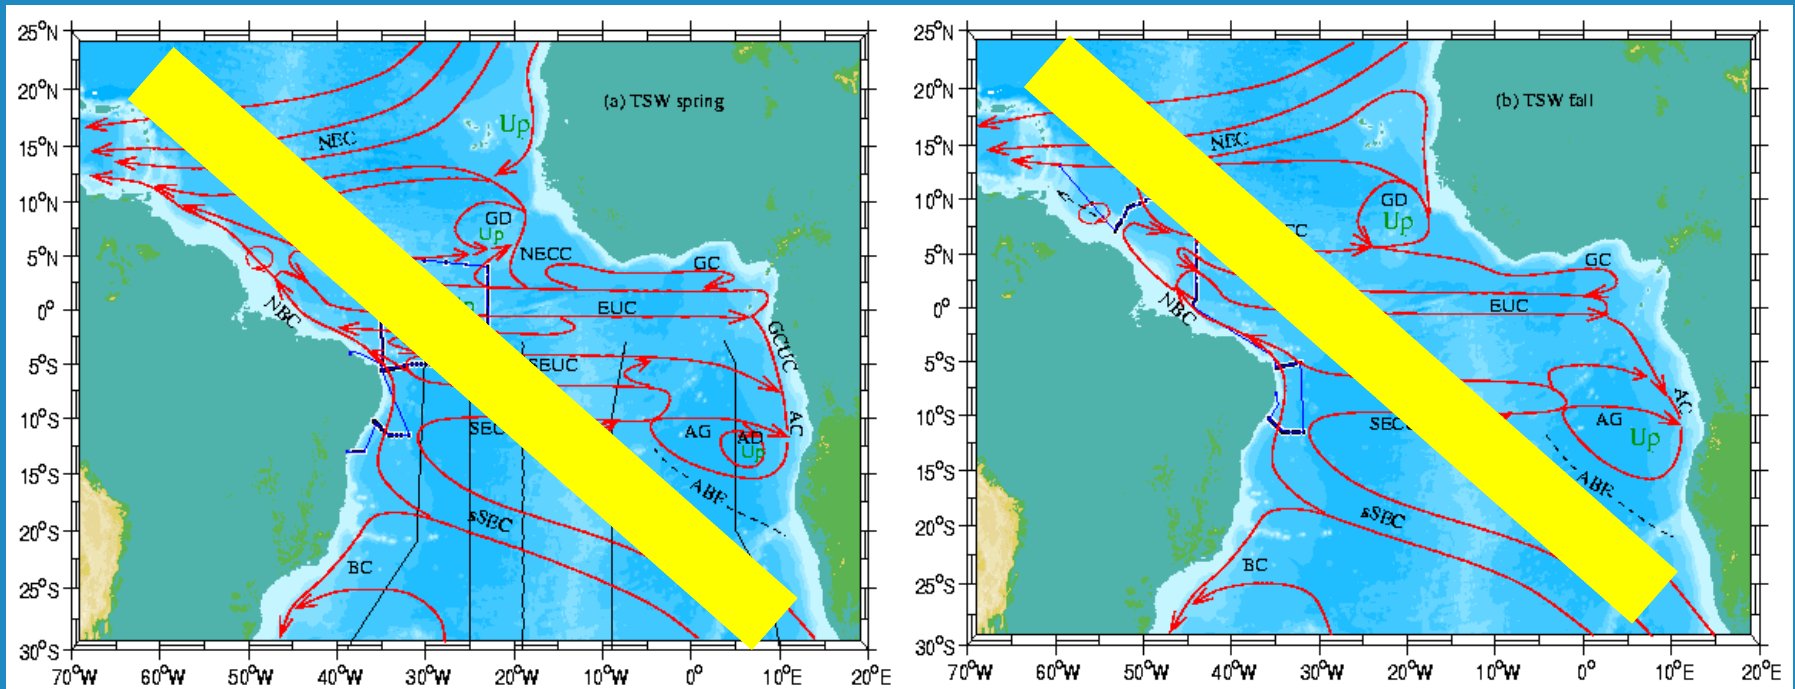

- Investigation of the variability of zonal currents in the tropical Atlantic to aid in the study of the role of upper ocean dynamics on sea surface temperature.
- Meridional water mass transfer across the equator.
- Investigation of the meridional heat transport across 30-35S.

# IMPROVEMENTS

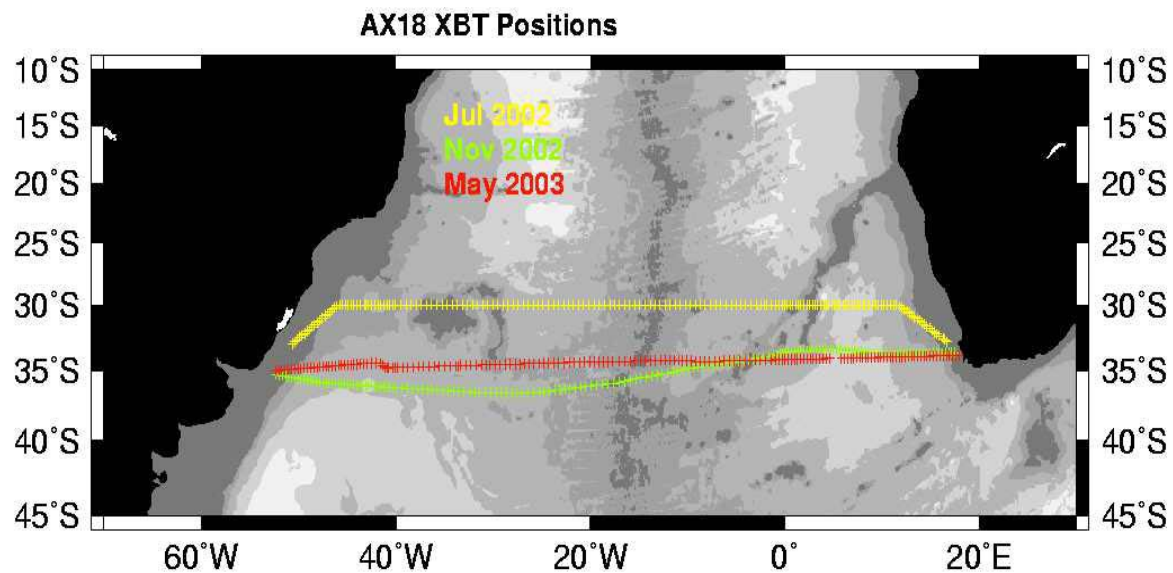

- *Intermediate to high density XBT deployment to Cape Town, underway*
- *Include TSG, too problematic, expensive*
- *Include XCTD, expensive, not included in current budget*
- *Include deeper XBTs, to 2000 m deep, expensive, redesign of autolaunchers, not included in current budget*
- *More profiling float data, depending on funding and interest*

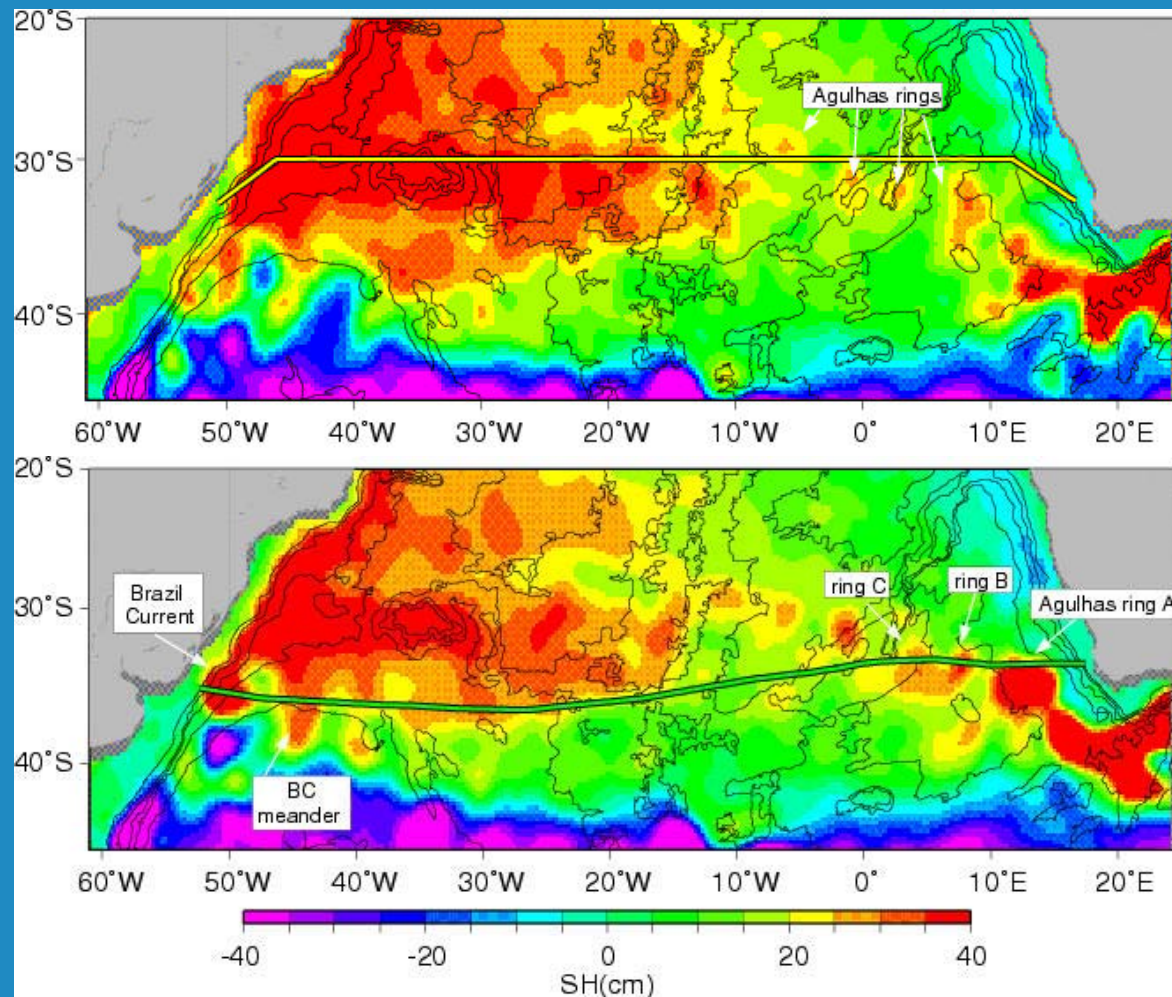

# Current and Immediate future work

- \* Obtain mean locations, transports, from monthly mean temperature sections.
- \* Relationship between surface currents and sea height signature.
- \* Investigate and (maybe) quantify the effect of waves in the synoptic temperature sections, the dynamic height and transport estimates.
- \* Compare our results with estimates from drifters and CM in PIRATA mooring (33°W).
- \* Compare our results with estimates obtained from numerical models.
- \* Use these results to improve the methodology used to monitor surface currents in NRT from altimetry in CoastWatch.

# The first three transects of AX18

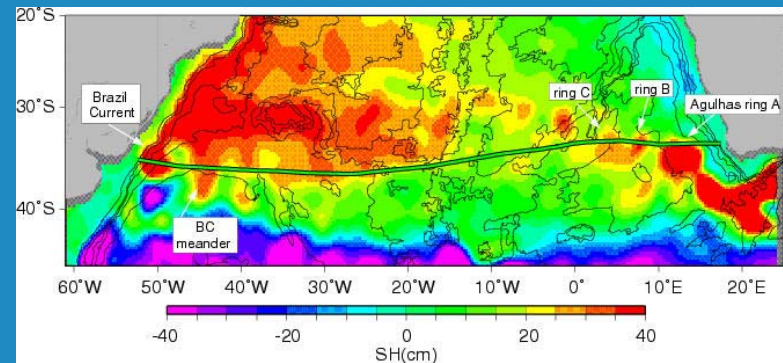

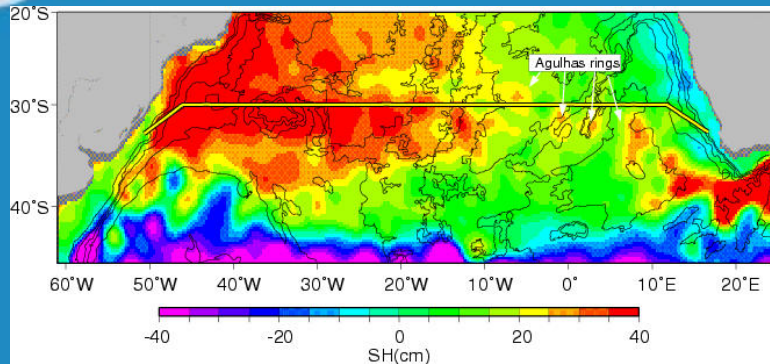

# The transects and the upper ocean dynamics

# Cumulative geostrophic transports

# AX18 and the Meridional heat flux in the Atlantic Ocean

In the South Atlantic the meridional heat flux is uncertain, estimates vary between -0.4 and +0.9 PW.

To better understand the global ocean thermohaline circulation and its impact on climate it is necessary to reduce the heat flux uncertainty in the South Atlantic

# Current and Immediate future work

- **Validate altimeter estimates of the transport of the Brazil and Agulhas currents.**
- **Validate altimeter estimates of the motion of the Brazil Current front.**
- **Continue with the estimates of meridional heat transport across 35°S.**
